

# Chapter 2: Processes Management

# Objectives

- ▶ To introduce the notion of a process -- a program in execution, which forms the basis of all computation
- ▶ To describe the various features of processes, including scheduling, creation and termination, and communication.
- ▶ OS must provide various provisions for synchronization, communication, and deadlock handling.

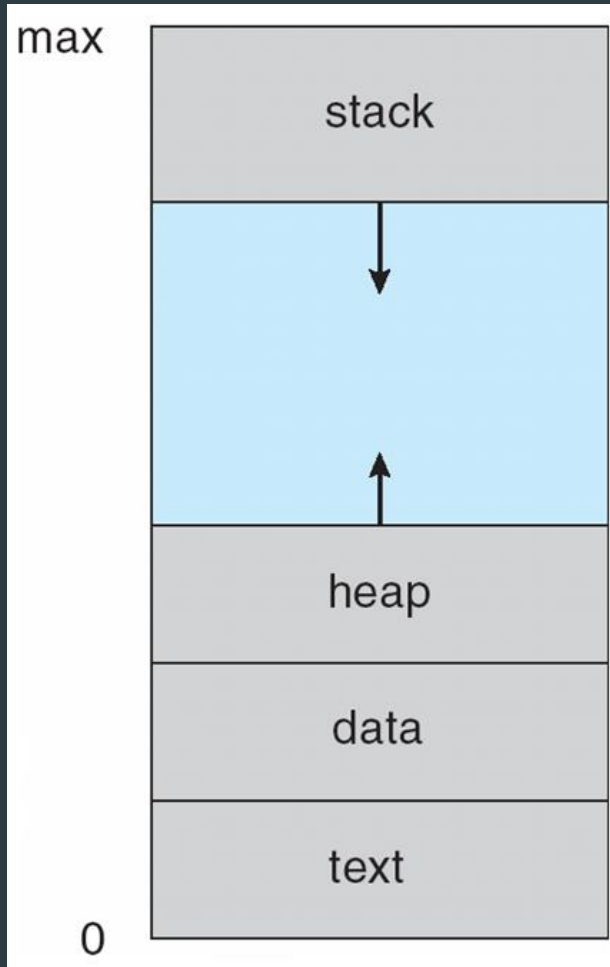

# Process Concept

- ▶ An operating system executes a variety of programs:
  - ▶ Batch system - **jobs**
  - ▶ Time-shared systems - **user programs or tasks**
- ▶ **Process** - a program in execution; process execution must progress in a sequential fashion.
- ▶ Multiple parts of a process itself:
  - ▶ *The program code*, also called the **text section**
  - ▶ *Current activity represented as a* **program counter**
  - ▶ Contents of the processor's registers.
  - ▶ **Stack** containing temporary data
    - ▶ Function parameters, return addresses, local variables
  - ▶ **Data section** containing global variables
  - ▶ **Heap** containing memory dynamically allocated during run time

# Process Concept (Cont.)

- ▶ Program is a *passive* entity stored on disk (**executable file**), the process is *active*
  - ▶ Program becomes process when executable file loaded into memory
- ▶ Execution of program started via GUI mouse clicks, command line entry of its name, etc
- ▶ One program can be several processes
  - ▶ Consider multiple users executing the same program

# Process in Memory

**Stack:** contains temporary data(function parameters, return addresses, local variables)

**Heap:** memory allocated dynamically.

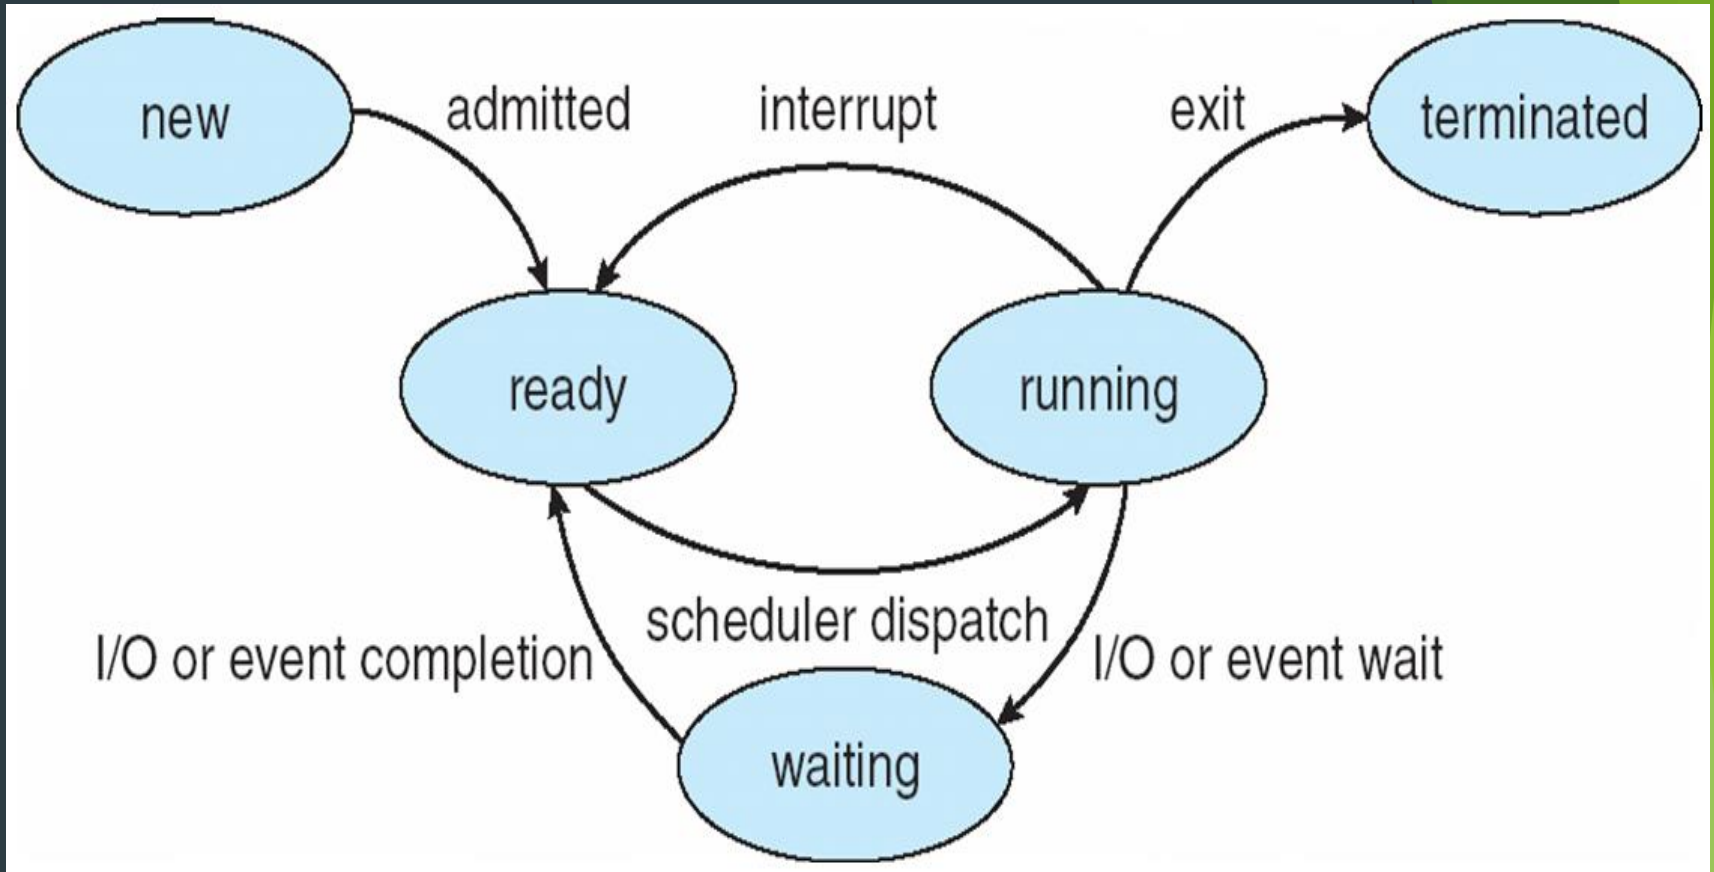

**Data:** global variables.

**Text:** Pgm instructions

# Process State

- ▶ As a process executes, it changes **state**
  - ▶ **new**: The process is being created
  - ▶ **running**: Instructions are being executed
  - ▶ **waiting**: The process is waiting for some event to occur
  - ▶ **ready**: The process is waiting to be assigned to a processor
  - ▶ **terminated**: The process has finished execution

# Diagram of Process State

# Process Control Block (PCB)

Information associated with each process

(also called **task control block**)

- ▶ Process state - running, waiting, etc
- ▶ Program counter - address/ location of instruction to execute next
- ▶ CPU registers - contents of all process-centric registers, contain addresses to help the process start where it had left.
- ▶ CPU scheduling information - priorities, scheduling queue pointers
- ▶ Memory-management information - memory allocated to the process
- ▶ Accounting information - CPU used, clock time elapsed since start, time limits, no. of processes
- ▶ I/O status information - I/O devices allocated to process, list of open files

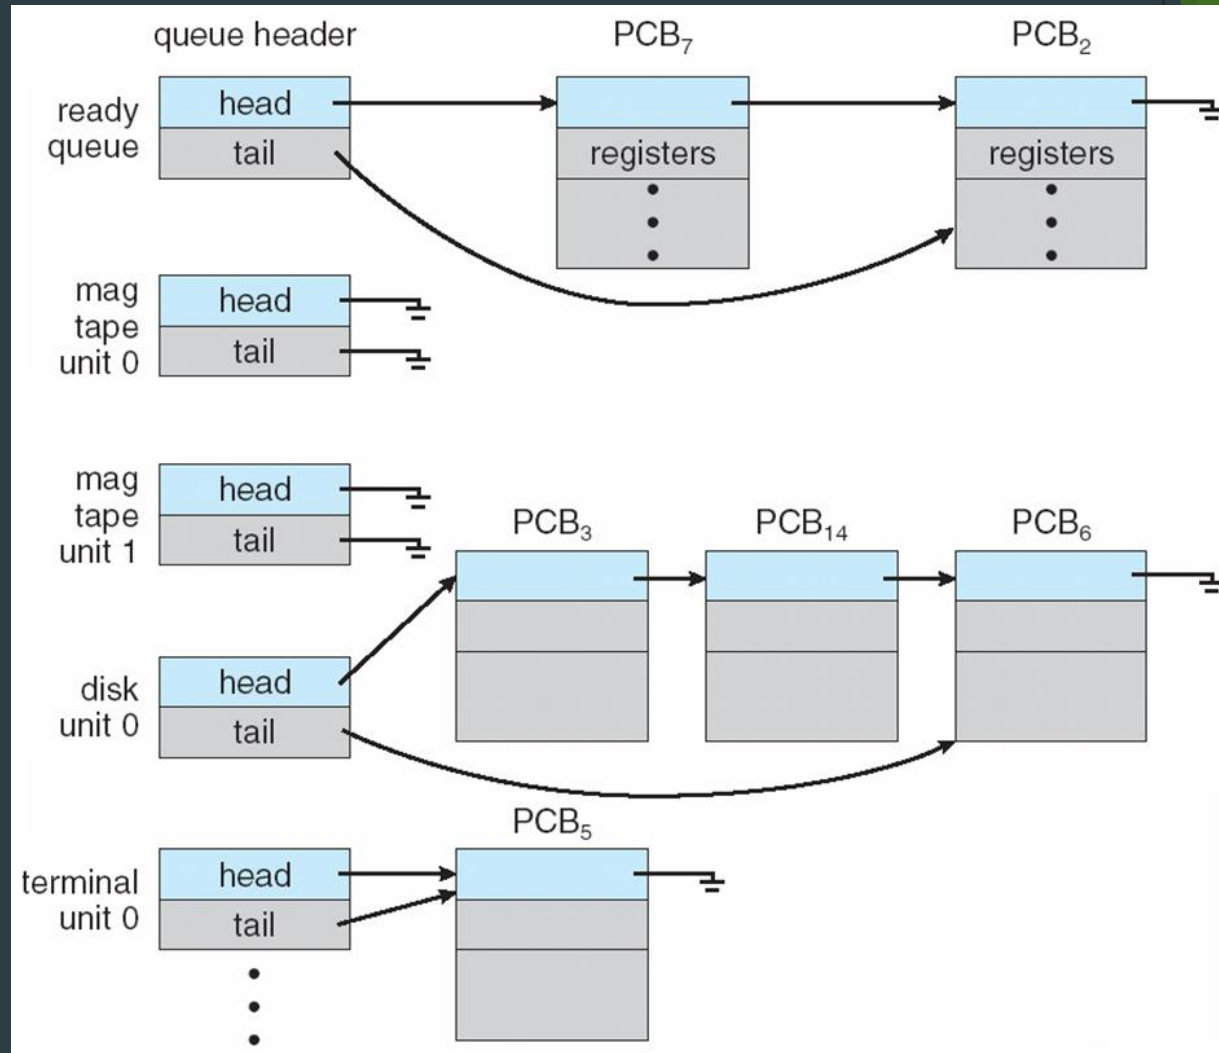

# CPU Switch From Process to Process

# Process Scheduling

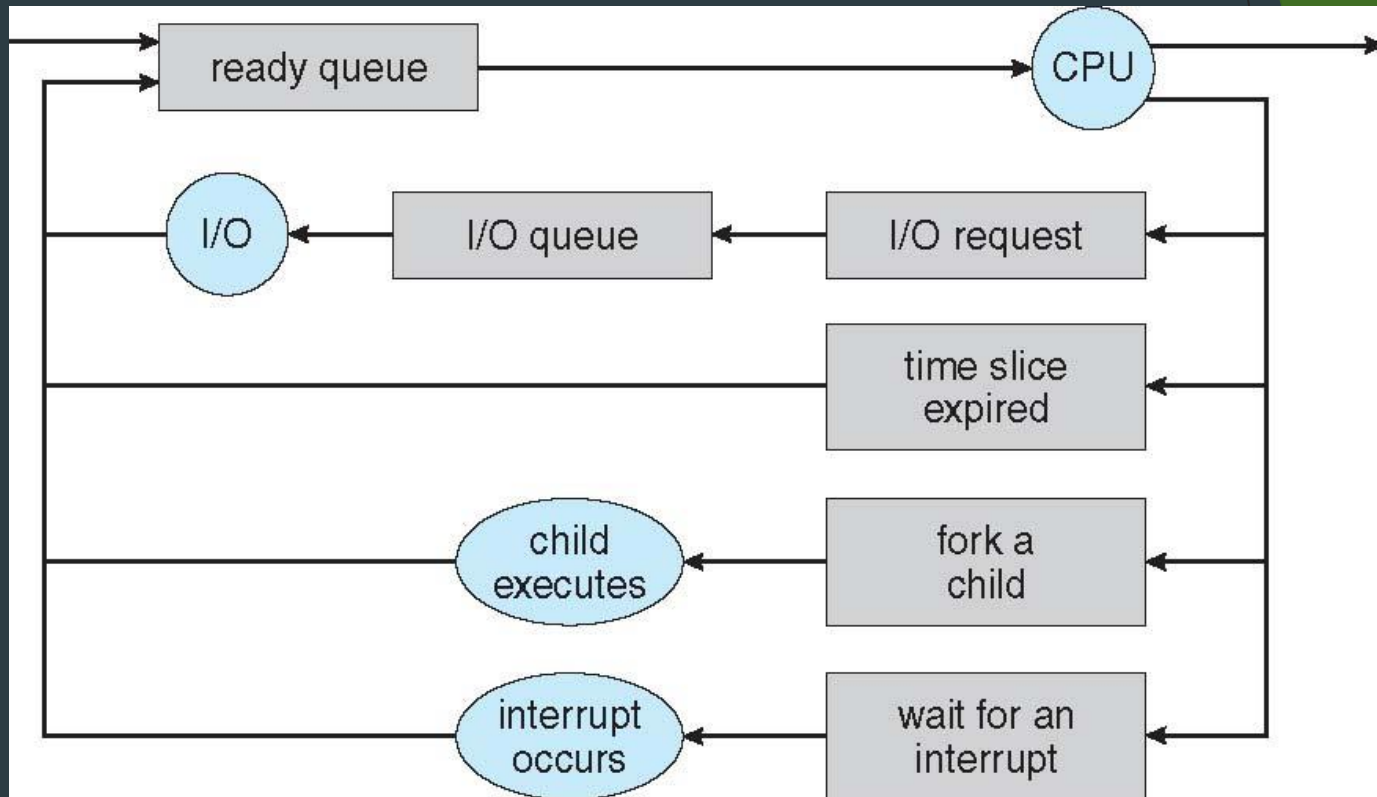

- ▶ Maximize CPU use, quickly switch processes onto CPU for time sharing
- ▶ **Process scheduler** selects among available processes for the next execution on CPU
- ▶ Maintains **scheduling queues** of processes
  - ▶ **Job queue** - set of all processes in the system
  - ▶ **Ready queue** - set of all processes residing in main memory, ready and waiting to execute
  - ▶ **Device queues** - a set of processes waiting for an I/O device
  - ▶ Processes migrate among the various queue time-sharing

## Ready Queue And Various I/O Device Queues

# Representation of Process Scheduling

- Queueing diagram represents queues, resources, flows

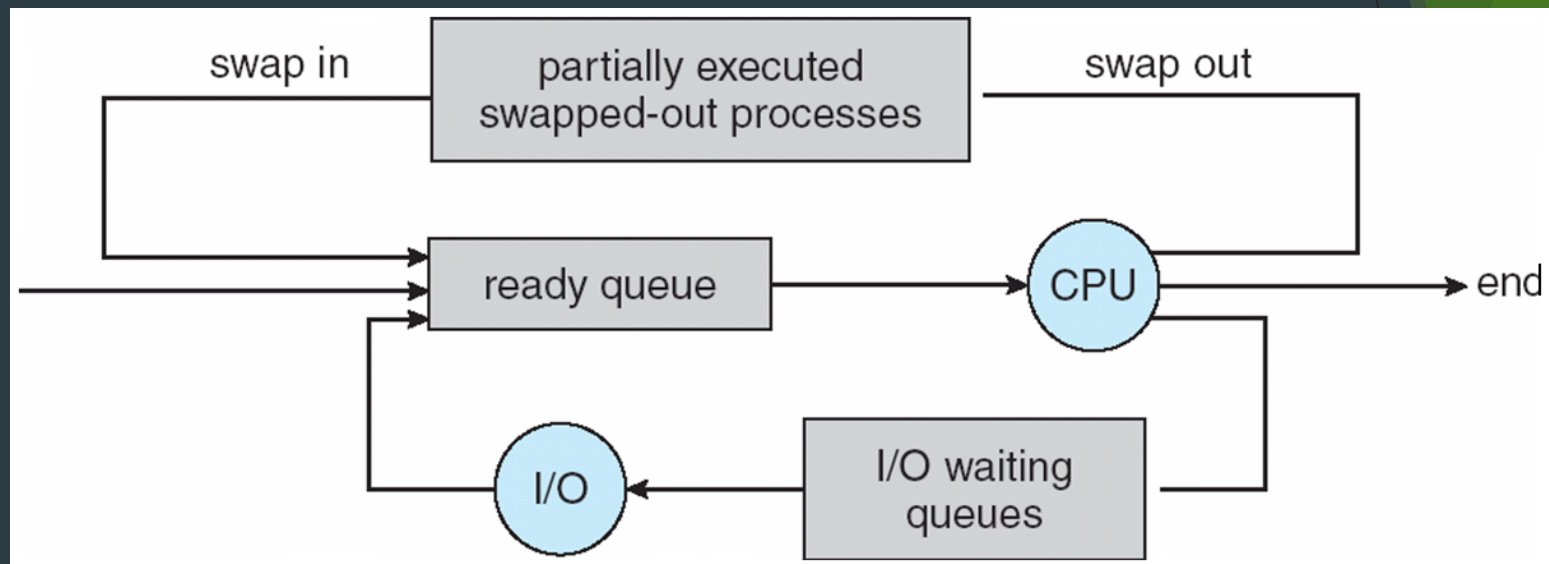

# Schedulers

- ▶ **Short-term scheduler** (or **CPU scheduler**) - selects which process should be executed next and allocates CPU
  - ▶ Sometimes the only scheduler in a system
  - ▶ Short-term scheduler is invoked frequently (milliseconds)  $\Rightarrow$  (must be fast)
- ▶ **Long-term scheduler** (or **job scheduler**) - selects which processes should be brought into the ready queue
  - ▶ Long-term scheduler is invoked infrequently (seconds, minutes)  $\Rightarrow$  (may be slow)
  - ▶ The long-term scheduler controls the **degree of multiprogramming**
- ▶ Processes can be described as either:
  - ▶ **I/O-bound process** - spends more time doing I/O than computations, many short CPU bursts
  - ▶ **CPU-bound process** - spends more time doing computations; few very long CPU bursts
- ▶ Long-term scheduler strives for good *process mix*

# Addition of Medium Term Scheduling

- **Medium-term scheduler** can be added if degree of multiple programming needs to decrease
  - Remove process from memory, store on disk, bring back in from disk to continue execution: **swapping**

# Context Switch

- ▶ When CPU switches to another process, the system must **save the state** of the old process and load the **saved state** for the new process via a **context switch**
- ▶ **Context** of a process represented in the PCB
- ▶ Context-switch time is overhead; the system does no useful work while switching
  - ▶ The more complex the OS and the PCB → the longer the context switch
- ▶ Time dependent on hardware support
  - ▶ Some hardware provides multiple sets of registers per CPU → multiple contexts loaded at once
